Abstract

Oats are a rich source of β -glucan, a viscous, soluble fibre recognised for its cholesterol-lowering properties, and are associated with reduced risk of CVD. Our objective was to conduct a systematic review and meta-analysis of randomised-controlled trials (RCT) investigating the cholesterol-lowering potential of oat β -glucan on LDL-cholesterol, non-HDL-cholesterol and apoB for the risk reduction of CVD. MEDLINE, Embase, CINAHL and Cochrane CENTRAL were searched. We included RCT of ≥3 weeks of follow-up, assessing the effect of diets enriched with oat β -glucan compared with controlled diets on LDL-cholesterol, non-HDL-cholesterol or apoB. Two independent reviewers extracted data and assessed study quality and risk of bias. Data were pooled using the generic inverse-variance method with random effects models and expressed as mean differences with 95 % CI. Heterogeneity was assessed by the Cochran's Q statistic and quantified by the I^2 -statistic. In total, fifty-eight trials (n 3974) were included. A median dose of 3·5 g/d of oat β-glucan significantly lowered LDL-cholesterol (-0·19; 95 % CI -0·23, -0·14 mmol/l, P < 0·00001), non-HDL-cholesterol (-0·20; 95 % CI -0·26, -0·15 mmol/l, P < 0·00001) and apoB (-0·03; 95 % CI -0·05, -0·02 g/l, P < 0.0001) compared with control interventions. There was evidence for considerable unexplained heterogeneity in the analysis of LDL-cholesterol ($I^2 = 79\%$) and non-HDL-cholesterol ($I^2 = 99\%$). Pooled analyses showed that oat β -glucan has a lowering effect on LDL-cholesterol, non-HDL-cholesterol and apoB. Inclusion of oat-containing foods may be a strategy for achieving targets in CVD reduction.

Key words: Oats: β -Glucan: Cholesterol-lowering properties: CVD: Systematic reviews and meta-analyses

Oats are a rich source of β -glucan, a viscous, soluble fibre recognised for its cholesterol-lowering properties. The attenuation of blood cholesterol levels by oats was first reported in 1963 in a study that substituted white bread for oat bread containing 140 g of rolled oats (1). Since then, a large number of studies have been conducted to assess the effects of oats on cholesterol levels, especially LDL-cholesterol, for the reduction of CVD risk. On the basis of the extensive evidence relating an inverse association between β -glucan intake and LDLcholesterol, several countries have currently approved health claims of oat β -glucan and its LDL-cholesterol-lowering effect or CVD risk reduction (2-6).

At present, the primary lipid target for CVD risk reduction is LDL-cholesterol, with non-HDL-cholesterol and apoB as alternate targets. However, it has been suggested that non-HDL-cholesterol and apoB may be more relevant targets as non-HDL-cholesterol contains all atherogenic cholesterol and there is one apoB on all atherogenic lipoprotein particles. Furthermore, both non-HDL-cholesterol and apoB have been shown to be highly correlated with CVD risk, especially when LDL-cholesterol appears to be within the normal range⁽⁷⁾, and have been added to the Third Report of the National Cholesterol Education Program - Adult Treatment Panel and the Canadian Cardiovascular Society (CCS) lipid guidelines as alternate lipid targets for CVD risk reduction^(8,9).

In contrast to the established relationship between oat β -glucan and LDL-cholesterol, there is currently little understanding of the relationship between oat β -glucan and alternate markers of CVD risk - that is, non-HDL-cholesterol and apoB. The objective of this study was to conduct a systematic review and meta-analysis of randomised-controlled trials (RCT) to analyse the evidence of the effect of oat β -glucan on

Abbreviations: MD, mean differences; MQS, Heyland Methodological Quality Score; RCT, randomised-controlled trials.

LDL-cholesterol, as well as for the first time on non-HDL-cholesterol and apoB, for CVD risk reduction.

Methods

Protocol and registration

The Cochrane Handbook for Systematic Reviews of Interventions was used to plan and conduct this meta-analysis (10). Results were reported in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analysis guidelines⁽¹¹⁾. The review protocol is available online at ClinicalTrials.gov (registration no. NCT02068248).

Search strategy and data sources

MEDLINE, Embase, CINAHL and the Cochrane Central Register of Controlled Trials were searched, using the search strategy presented in the online Supplementary Table S1, through 5 November 2015, to identify RCT investigating the effects of oat β -glucan on LDL-cholesterol, non-HDL-cholesterol or apoB. Manual searches of references supplemented the electronic search. One unpublished trial from our group was included in the analysis⁽¹²⁾. No language restrictions were imposed.

Study eligibility

All titles and abstracts were initially assessed according to inclusion and exclusion criteria outlined in the online Supplementary Table S2. In brief, only RCT that investigated the effects of supplementing β -glucan from oat products on LDLcholesterol, non-HDL-cholesterol and/or apoB were included in the analysis (13,14). Trials that did not report non-HDLcholesterol but provided enough information to permit the calculation of non-HDL-cholesterol (total cholesterol (TC)-HDL-cholesterol) were also considered. Included trials involved any population, had a minimum follow-up period of 3 weeks, as per the United States Food and Drug Administration (US FDA)^(13,15), administered any dose of β -glucan and provided enough information to calculate a treatment effect.

Data extraction and quality assessment

H. V. T. H. and A. Z. independently reviewed all studies that passed the initial assessment. A standardised proforma was used to extract relevant data including sample size, subject characteristics (health status, sex, age, weight, etc.), study setting (inpatient/outpatient), study design (parallel/crossover), follow-up duration, β -glucan dose, comparator, background diet, energy balance and funding source. If the β -glucan content was not reported, oat bran and whole oats were estimated at 6.9 and $5.0\%^{(16,17)}$ β -glucan, respectively, and oat soluble fibre was estimated at $92.5\% \beta$ -glucan⁽¹⁸⁾. The mean and standard deviation values were extracted for LDL-cholesterol, non-HDL-cholesterol and apoB at baseline and follow-up for both control and intervention groups. When standard deviation values were not reported, they were derived from available data (95% CI, P-values, t or F statistics, SEM) using standard formulae⁽¹⁰⁾. If available, mean change from baseline and standard deviation values for both groups, mean end difference and standard deviation values, and/or mean change from baseline difference and standard deviation values between groups were also extracted.

The Heyland Methodological Quality Score (MQS) was used to assess study quality⁽¹⁹⁾. Points were given on the basis of methods (randomisation, blinding and analysis), sample (selection, comparibility and follow-up) and intervention (protocol, co-intervention and cross-overs) and a maximum of 13 points could be received. Trials that received scores of ≥8 were considered to be of higher quality.

The Cochrane Risk of Bias Tool was used to assess the study risk of bias⁽¹⁰⁾. Domains of bias assessed were sequence generation, allocation concealment, blinding, outcome data and outcome reporting. Trials were considered high risk when methodological flaws were likely to have affected the true outcome, low risk if the flaw was deemed inconsequential and unclear risk when insufficient information was provided to permit judgement. Authors were contacted for additional information where necessary. All disagreements on the MQS and Risk of Bias Tool were resolved by consensus.

Data management and analysis

Data were analysed using Review Manager (RevMan), version 5.3 (The Nordic Cochrane Centre, The Cochrane Collaboration), for primary analyses. The difference between the change from baseline values for the intervention and the control arms was derived from each trial for the end points of LDL-cholesterol, non-HDL-cholesterol and apoB. When non-HDL-cholesterol was not reported, it was calculated from aggregate data by subtracting HDL-cholesterol from TC. A previously developed formula was used to calculate sp for calculated values of non-HDL-cholesterol⁽²⁰⁾. If change from baseline values were not available, end-of-treatment values were used. For trials containing multiple intervention or control arms, a weighted average was applied to combine them in order to create a single pair-wise comparison and to mitigate the unit-of-analysis error⁽¹⁰⁾. Paired analyses were conducted for all cross-over studies⁽²¹⁾. Where necessary, a pooled correlation coefficient was derived and used for calculation of an imputed so for the between-treatment difference. Correlation coefficients between baseline and end-of-treatment values within each individual cross-over trial were derived from the reported within- and between-treatment so according to a published formula (21). These correlation coefficients were transformed into z-scores and sp, meta-analysed using inverse-variance weighing and back-transformed to derive the pooled correlation coefficient. For end points, when a pooled correlation coefficient for imputing missing sp could not be derived, a value of 0.50 was assumed, as it is a conservative estimate for an expected range of 0-1. The values derived from each trial were pooled and analysed for LDL-cholesterol, non-HDL-cholesterol and apoB using the generic inverse-variance method with random effects models, which were used even in the absence of statistically significant between-study heterogeneity, as they yield more conservative summary effect estimates in the presence of

residual heterogeneity. Data are expressed as mean differences (MD) with 95% CI. Furthermore, results are presented separately according to individual study inclusion criteria. The hypercholesterolic group included studies that recruited participants who were hypercholesterolaemic, and the unclassified group included studies that did not specify that participants had to be hypercholesterolaemic. A two-sided *P*-value <0.05 was set as the level of significance for comparisons of MD.

Inter-study heterogeneity was tested using Cochran's Q statistic and quantified using the I^2 -statistic with a significance level set at P < 0.10. I^2 values < 50, ≥ 50 to < 75 and ≥ 75 % were considered to be evidence for 'moderate,' 'substantial' and 'considerable' heterogeneity, respectively (10). Sources of heterogeneity were explored using sensitivity and subgroup analyses. To determine whether a single trial exerted undue influence on the overall results, sensitivity analyses were performed in which each individual trial was removed from the meta-analysis and the effect size was re-calculated with the remaining trials. Sensitivity analyses were also undertaken using correlation coefficients of 0.25, 0.50 and 0.75 to determine whether the overall results were robust to the use of different derived correlation coefficients in paired analyses of cross-over trials. A priori subgroup analyses (continuous and categorical) were conducted for baseline values of LDL-cholesterol, non-HDL-cholesterol and apoB within the intervention arm, dose, design, follow-up and study quality, Metaregression was performed to assess the significance of subgroup effects with STATA software, version 13 (StataCorp LP), with a significance level set at P < 0.05.

Publication bias was investigated by visual inspection of funnel plots and quantitatively assessed using Egger's and Begg's tests, where P < 0.05 was considered evidence for small study effects.

Funnel plots were used to display the relative treatment effect and its 95% CI for each trial and dose amount and for the overall random-effects meta-analyses.

Results

Search results

The search strategy initially yielded 8190 publications, of which 269 were reviewed in full and fifty-eight $(n\ 3974)$ were included in the final meta-analysis (Fig. 1). In total, fifty-six trials reported data on LDL-cholesterol $(n\ 3745)$ and seventeen on apoB $(n\ 1070)$. Only one trial reported data on non-HDL-cholesterol; however, fifty-six other trials reported enough information to calculate non-HDL-cholesterol $(n\ 3926)$.

Trial characteristics

The characteristics of the included trials are summarised in Table 1. Trials were conducted in both in-patient and outpatient settings with twenty-five in North American (nineteen in USA, five in Canada and one in Mexico), nineteen in Europe (six in Sweden, four in England, three in the Netherlands, two in France and one each in Denmark, Finland, Germany and Greece), eight in Australia and New Zealand, three in Asia (two in China and one in Thailand), one in South America

(Venezuela) and one in the Middle East (Iran). All trials were randomised, with 66% (thirty-eight trials) utilising a parallel design and 34% (twenty trials) utilising a cross-over design. Participants were generally middle aged (median age = 50·6 (range: 10–67) years) with an approximately equal number of men and women. Participants were slightly overweight (median BMI = 26·8 (range: $22\cdot8-32\cdot2$) kg/m²), despite only 4 four trials recruiting on the basis of overweight/obese. Two-thirds of the trials (thirty-nine trials) were conducted in hypercholester-olaemic individuals. The dose of oat β -glucan ranged from 0·9 to $10\cdot3$ g/d with a median dose of $3\cdot5$ g/d. Treatment duration ranged from 3 to 12 weeks with the median length being 6 weeks for trials reporting LDL-cholesterol and non-HDL-cholesterol and 5 weeks for trials reporting apoB.

Very few studies (nine trials, 16%) were considered to be of higher quality (MQS≥8). Lack of or poor description of randomisation, patient selection, protocol analysis and absence of double-blinding contributed to lower scores (online Supplementary Table S3). The Cochrane Risk of Bias Tool (online Supplementary Fig. S1 and Table S4) showed that seventeen trials (29%) had low risk of bias and forty-two trials (71%) had unclear risk of bias for random sequence generation. A total of thirteen trials (22%) had low risk of bias, and forty-six trials (78%) were unclear for allocation concealment. Moreover, thirty trials (50%) had high risk of bias, twenty-one trials (36%) had low risk of bias and eight trials (14%) had unclear performance bias (blinding of participants and personnel); five trials (8%) has high risk of bias, forty-nine trials (84%) had low risk of bias and five trials (8%) had unclear risk of bias for attrition bias. The majority of trials (93%) had low risk of bias for reporting bias, whereas the remainder of the trials (7%) had unclear risk of bias for these items. Funding of trials included agency (26%), agency-industry (16%), industry (34%) sources or were not reported (24%).

Effect on LDL-cholesterol

The effect of oat β -glucan on LDL-cholesterol is shown in Fig. 2. Overall, a significant LDL-cholesterol reduction was observed with a median dose of 3.5 g/d for a median duration of 6 weeks (MD=-0.19 mmol/l; 95 % CI -0.23, -0.14; P < 0.00001). However, substantial evidence of inter-study heterogeneity was present in the overall analysis ($I^2 = 79$ %; P < 0.00001). Systematic removal of individual trials did not alter the results.

Categorical *a priori* subgroup analyses revealed that the LDL-cholesterol lowering effect of oat β -glucan was modified by both study design (between-group MD=0·09 mmol/l; 95% CI 0·01, 0·17; P=0·03) – studies that utilised a cross-over design demonstrated an MD of $-0\cdot25$ mmol/l (95% CI $-0\cdot31$, $-0\cdot18$), whereas studies that utilised a parallel design showed an MD of $-0\cdot16$ mmol/l (95% CI $-0\cdot20$, $-0\cdot11$) – and study duration (between-group MD=0·09 mmol/l; 95% CI 0·02, 0·17; P=0·03) – studies where oat β -glucan was administered for <6 weeks demonstrated an MD of $-0\cdot24$ mmol/l (95% CI $-0\cdot29$, $-0\cdot18$), whereas studies that administered oat β -glucan for 6 weeks or more showed an MD of $-0\cdot15$ mmol/l (95% CI $-0\cdot20$, $-0\cdot09$), (online Supplementary Fig. S2). Continuous meta-regression analyses demonstrated an inverse association between baseline

Fig. 1. Flow of literature. Summary of search and selection process.

LDL-cholesterol and treatment differences for LDL-cholesterol $(\beta = -0.09 \text{ mmol/l}; 95\% \text{ CI } -0.15, -0.03; P = 0.004)$ (online Supplementary Table S5). Heterogeneity remained significant, and could not be explained by subgroup analyses.

Effect on non-HDL-cholesterol

The effect of oat β -glucan on non-HDL-cholesterol is shown in Fig. 3. Overall, non-HDL-cholesterol was significantly reduced by $-0.20 \,\text{mmol/l}$ (95% CI -0.26, -0.15), P < 0.00001, with a median dose of 3.5 g/d for a median duration of 6 weeks. Considerable evidence of inter-study heterogeneity was present in the overall analysis $(I^2 = 99\%; P < 0.00001)$. Systematic removal of individual trials did not alter the results.

Categorical a priori subgroup analyses revealed that the non-HDL-cholesterol lowering was not modified by dose, study duration, study design, MQS scores or baseline non-HDLcholesterol levels (online Supplementary Fig. S3). Furthermore, continuous meta-regression analyses did not reveal associations between dose, treatment duration or baseline non-HDLcholesterol levels (online Supplementary Table S5).

Effect on apoB

The effect of oat β -glucan on apoB is shown in Fig. 4. Overall, there was evidence of a significant lowering of apoB with a median dose of 3.5 g/d for a median duration of 5 weeks (MD = -0.03 g/l; 95% CI -0.05, -0.02; P < 0.0001) withmoderate evidence of heterogeneity ($I^2 = 38\%$; P = 0.06). Systematic removal of individual trials did not alter the results.

Categorical a priori subgroup analyses revealed that the apoB lowering by oat β -glucan was not modified by dose, study duration, study design, MQS scores or baseline apoB levels (online Supplementary Fig. S4). Furthermore, continuous meta-regression analyses did not reveal associations between dose, treatment duration or baseline apoB levels (online Supplementary Table S5).

Publication bias

Funnel plots for LDL-cholesterol, non-HDL-cholesterol and apoB are shown in Fig. 5. Visual inspection of funnel plots suggested minor asymmetry in the LDL-cholesterol and non-HDL-cholesterol analyses, with tendencies for the publication of small and/or imprecise trials favouring oat β -glucan for both. This was confirmed by Begg's tests (P=0.061) for LDLcholesterol; however, neither Egger's (P=0.381) nor Begg's (P=0.528) test was significant for non-HDL-cholesterol.

Discussion

The present systematic review and meta-analysis of fifty-eight trials involving 3974 participants assessed the effects of oat β -glucan on clinical lipid targets for CVD risk reduction (LDLcholesterol, non-HDL-cholesterol and apoB). Diets enriched with a median dose of $3.5 \,\mathrm{g/d}$ of β -glucan were found to modestly improve LDL-cholesterol (-4.2%), non-HDLcholesterol (-4.8%) and apoB (-2.3%), compared with

Brown et al. (79) were the first to undertake a comprehensive meta-analysis of all viscous, soluble fibre types on cholesterol. Although the main objective was to study the cholesterollowering effect of all viscous, soluble fibre types, it was, nevertheless, the first to consolidate data on oats and

Oat β -glucan and lipids for CVD risk reduction

[†] Whole oats can be oatmeal, instant oats, oat flakes or whole oat flour.

[‡] The number of participants listed for each trial is the number of participants that completed the trial, and therefore the number used in our analyses and the number used for the reported baseline data (age and BMI), unless otherwise indicated with '*'.

[§] Dose of β -glucan.

Il Trials with an MQS≥8 were considered to be of higher quality.

[¶] Agency funding is that from government, university or not-for-profit health agency sources.

N, Number of participants in each treatment group.

Fig. 5. Publication bias funnel plots. Funnel plots assessing publication bias and effect of small and/or imprecise study effects for (a) LDL-cholesterol, (b) non-HDL-cholesterol and (c) apoB. ——, the pooled effect estimate expressed as the mean difference for each analysis; -----, pseudo-95 % Cl. *P*-values are derived from quantitative assessment of publication bias by Egger's and Begg's tests.

LDL-cholesterol levels. In total, twenty-five studies investigating the cholesterol-lowering effect of oats were included in a subgroup analysis, and the authors reported a significant overall LDL-cholesterol reduction of $-0.037 \, \text{mmol/l}$ (95% CI-0.047, -0.017) per g of oat fibre. This is approximately equivalent to $-0.13 \, \text{mmol/l}$ per $3.5 \, \text{g}$, $30 \, \text{%}$ less than what was observed in our current study (Fig. 2). However, as the results from this meta-analysis were reported as mmol/l of LDL-cholesterol reduction per gram of soluble fibre, they cannot be directly compared with the results of the current study.

In the most recent meta-analysis of oat β -glucan and LDL-cholesterol⁽¹⁸⁾, the authors included twenty-eight RCT and reported an LDL-cholesterol reduction of -0.25 mmol/l (-6%), whereas this study demonstrated a reduction of -0.19 mmol/l (-4.2%). This discrepancy could be due to differences in study selection criteria. Whitehead et al. only included RCT that administered ≥ 3 g/d of oat β -glucan, which resulted in a median daily dose of 5.1 g, whereas the current meta-analysis included studies of all doses and observed a median dose of 3.5 g/d. When the results were examined on a per gram basis, LDL-cholesterol reductions were on par (Whitehead et al.: $-0.050 \,\mathrm{mmol/l}\ v$., our study: $-0.054 \,\mathrm{mmol/l}$ per g of oat β -glucan) despite the differences in dose. Interestingly, our meta-regression analysis indicated a significant inverse association between dose and LDL-cholesterol levels (online Supplementary Table S4). Furthermore, when dose was categorised according to Health Canada and US FDA recommendations ($<3.0 v. \ge 3.0 g/d$), there was a trend towards treatment modification by dose (P=0.051), such that LDL-cholesterol reduction was almost double in trials that administered $\geq 3.0 \,\mathrm{g/d}$ of oat β -glucan compared with those that administered <3.0 g/d (online Supplementary Fig. S2). These results further support the health claims set by Health Canada and US FDA that cholesterol lowering can be achieved with a minimum of 3 g/d of oat β -glucan.

This is the first meta-analysis of RCT yielding information on the effect of oat β -glucan on non-HDL-cholesterol and apoB. These markers have been added to clinical practice guidelines^(8,9) on the basis that they are more highly associated with CVD risk than LDL-cholesterol⁽⁷⁾. Furthermore, the appreciation of these markers for CVD risk is especially important in adults with the metabolic syndrome and/or diabetes as LDLcholesterol is not typically elevated in this population. Pooled analyses demonstrated significant reductions of non-HDLcholesterol (-0.20 mmol/l (95 % CI -0.26, -0.15)) and apoB (-0.03 g/l (95% CI -0.05, -0.02)); however, the results are compromised by considerable unexplained heterogeneity. Interestingly, when trials were classified into the hypercholesterolaemic or unclassified group, of which more than a quarter of the studies were conducted in type 2 diabetes mellitus, both categories demonstrated significant reductions in non-HDLcholesterol and apoB. This is an important finding, considering that type 2 diabetes mellitus is generally not associated with increased LDL-cholesterol. Therefore, focusing on interventions that reduce non-HDL-cholesterol and apoB may be more practical and reliable for addressing the increased risk of CVD in type 2 diabetes mellitus.

Effect modification by baseline cholesterol levels has been previously described, such that cholesterol lowering by

 β -glucan is generally greater in those with hypercholesterolaemia (9). This was confirmed by our meta-regression analysis demonstrating a significant inverse association between baseline LDL-cholesterol levels and the extent of LDL-cholesterol reduction (online Supplementary Table S4). However, higher baseline levels of non-HDL-cholesterol or apoB were not significantly associated with greater reductions.

There are several limitations to the present meta-analysis that complicate the interpretation of the results. The first one being that the β -glucan content of oats was estimated for the majority of trials as it was not routinely analysed and reported. As β -glucan content varies significantly depending on genetics and environmental growing conditions (80,81), it is difficult to precisely measure the treatment effect when the majority of trials did not conduct a chemical analysis of the β -glucan content of their study products.

Second, the considerable heterogeneity that was observed in LDL-cholesterol and non-HDL-cholesterol was not explained by any of the a priori subgroup analyses. Nevertheless, considering the large number of studies included in this metaanalysis, high heterogeneity is inevitable. The studies included a wide range of food matrices that were used to administer oat β -glucan, several different processing and storage methods, varying molecular levels of β -glucan, etc., all of which are interrelated and significantly impact viscosity of the β -glucan, and thus its cholesterol-lowering potency. Furthermore, nutrition studies have not yet incorporated non-HDL-cholesterol into their primary analysis, despite the simple calculation. Therefore, in addition to all the previously mentioned sources of heterogeneity, the entire set of non-HDL-cholesterol data was mathematically imputed, which may have contributed to the increased heterogeneity.

Irrespective of the large heterogeneity associated with including studies that were conducted in a wide range of participants, in numerous countries, and used various common food products to administer the oat β -glucan, the results can be considered largely generalisable and indicative that the cholesterol-lowering benefits can be achieved by supplementing oat β -glucan into commonly consumed foods.

In conclusion, this systematic review and meta-analysis supports the dose-dependent intake of oat β -glucan for the reduction of LDL-cholesterol, non-HDL-cholesterol and apoB in middle-aged participants. Because of considerable unexplained heterogeneity, caution should be taken when interpreting the results. There is a need for larger, longer, high-quality RCT on the effect of oat β -glucan on blood cholesterol levels, especially non-HDL-cholesterol and apoB end points, and in participants with different metabolic phenotypes. Special attention should be paid to β -glucan molecular weight and content in these trials to allow for a more accurate assessment of the cholesterol-lowering properties of β -glucan.
